## Hadamard matrices and association schemes

- Goethals-Seidel (1970), regular symmetric Hadamard matrices with constant diagonal are equivalent to certain strongly regular graphs (symmetric association schemes of class 2 ).
From real $\left(\boldsymbol{H} \boldsymbol{H}^{\top}=\boldsymbol{n} \boldsymbol{I}\right)$ to complex $\left(\boldsymbol{H} \boldsymbol{H}^{*}=\boldsymbol{n} \boldsymbol{I}\right)$ :
real Hadamard $( \pm 1) \subset$ Butson-Hadamard (roots of unity)
$\subset$ Complex Hadamard (absolute value 1)
$\subset$ Inverse-orthogonal $=$ type II
- Jaeger-Matsumoto-Nomura (1998): type II matrices
- Chan-Godsil (2010): complex Hadamard
- Ikuta-Munemasa (2015): complex Hadamard

## Complex Hadamard matrices

An $\boldsymbol{n} \times \boldsymbol{n}$ matrix $\boldsymbol{H}=\left(\boldsymbol{h}_{\boldsymbol{i j}}\right)$ is called a complex Hadamard matrix if

$$
H H^{*}=n I \text { and }\left|h_{i j}\right|=1 \quad(\forall i, j)
$$

It is called a Butson-Hadamard matrix if all $\boldsymbol{h}_{\boldsymbol{i j}}$ are roots of unity. It is called a (real) Hadamard matrix if all $h_{i j}$ are $\pm 1$. The 5th workshop on Real and Complex Hadamard Matrices and Applications, July, 2017, Budapest, aimed at
(1) The Hadamard conjecture: a (real) Hadamard matrix exists for every order which is a multiple of 4 (yes for order $\leq 664$ ).
(2) Complete set of mutually unbiased bases (MUB) exists for non-prime power dimension? For example, 6.
(3) Understand the space of complex Hadamard matrices of order 6.

## Coherent Algebras and Coherent Configuration

Let $\boldsymbol{G}$ be a finite permutation group acting on a finite set $\boldsymbol{X}$. From the set of orbits of $\boldsymbol{X} \times \boldsymbol{X}$, one defines adjacency matrices

$$
A_{0}, A_{1}, \ldots, A_{d} \text { with } \sum_{i=0}^{d} A_{i}=J \text { (all-one matrix). }
$$

Then the linear span $\left\langle\boldsymbol{A}_{\mathbf{0}}, \boldsymbol{A}_{\mathbf{1}}, \ldots, \boldsymbol{A}_{\boldsymbol{d}}\right\rangle$ is closed under multiplication and transposition ( $\rightarrow$ coherent algebra, coherent configuration).
If $\boldsymbol{G}$ acts transitively, we may assume $\boldsymbol{A}_{\mathbf{0}}=\boldsymbol{I}(\rightarrow$ Bose-Mesner algebra of an association scheme).
If $\boldsymbol{G}$ contains a regular subgroup $\boldsymbol{N}$, we may identify $\boldsymbol{X}$ with $\boldsymbol{N}$, $\boldsymbol{A}_{i} \leftrightarrow \boldsymbol{T}_{i} \subseteq \boldsymbol{N}$, and

$$
N=\bigcup_{i=0}^{d} T_{i}, T_{0}=\left\{1_{N}\right\}, \quad \mathbb{C}[N] \supseteq\left\langle\sum_{g \in T_{i}} g \mid 0 \leq i \leq d\right\rangle .
$$

## Schur rings

$$
\begin{aligned}
N & =\bigcup_{i=0}^{d} T_{i}, \quad T_{0}=\left\{1_{N}\right\} \\
\mathbb{C}[N] & \mathcal{A}=\left\langle\sum_{g \in T_{i}} g \mid 0 \leq i \leq d\right\rangle \quad \text { (subalgebra). }
\end{aligned}
$$

$\mathcal{A}$ is called a Schur ring if, in addition

$$
\left\{T_{i}^{-1} \mid 0 \leq i \leq d\right\}=\left\{T_{i} \mid 0 \leq i \leq d\right\}
$$

where

$$
T^{-1}=\left\{t^{-1} \mid t \in T\right\} \quad \text { for } T \subseteq N
$$

Examples: $A G L(1, q)>G>N=G F(q)$ (cyclotomic).

## $A G L(1, q)>G>N=G F(\boldsymbol{q})$ (cyclotomic)

More generally,

$$
R: R^{\times}>G>N=R: \text { a ring. }
$$

In Ito-Munemasa-Yamada (1991), we wanted to construct an association scheme with eigenvalue a multiple of $i=\sqrt{-1}$. Not possible with $\boldsymbol{R}=\boldsymbol{G F}(\boldsymbol{q})$.

$$
\begin{aligned}
G F(p) & \hookrightarrow G F\left(p^{e}\right) \\
\mathbb{Z}_{p^{n}} & \hookrightarrow G R\left(p^{n}, e\right)
\end{aligned}
$$

A Galois ring $\boldsymbol{R}=\boldsymbol{G R}\left(\boldsymbol{p}^{n}, \boldsymbol{e}\right)$ is a commutative local ring with characteristic $\boldsymbol{p}^{n}$, whose quotient by the maximal ideal $\boldsymbol{p R}$ is $\boldsymbol{G F}\left(\boldsymbol{p}^{e}\right)$.

## Structure of $G R\left(p^{n}, e\right)$

Let $\boldsymbol{R}=\boldsymbol{G} \boldsymbol{R}\left(\boldsymbol{p}^{n}, \boldsymbol{e}\right)$ be a Galois ring. Then

$$
|R|=p^{n e},
$$

$\boldsymbol{p} \boldsymbol{R}$ is the unique maximal ideal,

$$
\begin{aligned}
\left|R^{\times}\right| & =|R \backslash p R|=p^{n e}-p^{(n-1) e}=\left(p^{e}-1\right) p^{(n-1) e} \\
R^{\times} & =\mathcal{T} \times \mathcal{U}, \quad \mathcal{T} \cong \mathbb{Z}_{p^{e}-1}, \quad|\mathcal{U}|=p^{(n-1) e}
\end{aligned}
$$

Now specialize $p^{n}=4$, consider $\boldsymbol{G R}(4, e)$.

## Structure of $G R(4, e)$

Let $\boldsymbol{R}=\boldsymbol{G R}(4, e)$ be a Galois ring of characteristic 4 . Then

$$
\begin{aligned}
|R| & =4^{e}, \\
2 R & \text { is the unique maximal ideal, } \\
\left|R^{\times}\right| & =|R \backslash 2 R|=4^{e}-2^{e}=\left(2^{e}-1\right) 2^{e}, \\
R^{\times} & =\mathcal{T} \times \mathcal{U}, \quad \mathcal{T} \cong \mathbb{Z}_{2^{e}-1}, \\
\mathcal{U} & =1+2 R \cong \mathbb{Z}_{2}^{e} .
\end{aligned}
$$

To construct a Schur ring, we need to partition

$$
R=R^{\times} \cup 2 R
$$

(into even smaller parts). In Ito-Munemasa-Yamada (1991), the orbits of a subgroup of the form $\mathcal{T} \times \mathcal{U}_{0}<\boldsymbol{R}^{\times}$were used. Ma (2007) also considered orbits of a subgroup containing $\mathcal{T}$.

## $\mathcal{U}_{0}$ as a subgroup of $\mathcal{U}$ of index $\mathbf{2}$

## $R=G R(4, e)$,

$2 \boldsymbol{R}$ is the unique maximal ideal,

$$
\boldsymbol{R}^{\times}=\mathcal{T} \times \mathcal{U}, \quad \mathcal{T} \cong \mathbb{Z}_{2^{e}-1}
$$

$$
\mathcal{U}=1+2 R \cong \mathbb{Z}_{2}^{e} \text { the principal unit group. }
$$

There is a bijection

So the "trace-0" additive subgroup of $\boldsymbol{G F}\left(\boldsymbol{2}^{e}\right)$ is mapped to $\mathcal{P}_{0}$ and $\mathcal{U}_{0}$ with $\left|2 R: \mathcal{P}_{0}\right|=\left|\mathcal{U}: \mathcal{U}_{0}\right|=2$.
Assume $\boldsymbol{e}$ is odd. Then $1 \notin$ "trace- 0 " subgroup, so $2 \notin \mathcal{P}_{0}$ and $-1=3 \notin \mathcal{U}_{0}$.

$$
\begin{aligned}
& G F\left(2^{e}\right)=R / 2 R \leftarrow \mathcal{T} \cup\{0\} \rightarrow 2 R \rightarrow \mathcal{U}, \\
& a+2 R \leftarrow a \quad \mapsto 2 a \mapsto 1+2 a .
\end{aligned}
$$

## Partition of $R=G R(4, e)$

Assume $e$ is odd. Then $2 \notin \mathcal{P}_{0},-1 \notin \mathcal{U}_{0}$.

$$
\begin{aligned}
\boldsymbol{R}^{\times} & =\mathcal{T} \times \mathcal{U}, \quad \mathcal{T} \cong \mathbb{Z}_{2^{e}-1} \\
2 R & =\mathcal{P}_{0} \cup\left(2+\mathcal{P}_{0}\right), \\
\mathcal{U} & =\mathcal{U}_{0} \cup\left(-\mathcal{U}_{0}\right) .
\end{aligned}
$$

Then $\mathcal{U}_{0}$ acts on $\boldsymbol{R}$, and the orbit decomposition is

$$
\begin{aligned}
R= & \left(\bigcup_{t \in \mathcal{T}} t \mathcal{U}_{0} \cup\left(-t \mathcal{U}_{0}\right)\right) \cup\left(\bigcup_{a \in 2 R}\{a\}\right) \\
= & \mathcal{U}_{0} \cup\left(-\mathcal{U}_{0}\right) \cup\left(\bigcup_{t \in \mathcal{T} \backslash\{1\}} t \mathcal{U}_{0}\right) \cup\left(\bigcup_{t \in \mathcal{T} \backslash\{1\}}\left(-t \mathcal{U}_{0}\right)\right) \\
& \cup\{0\} \cup\left(\mathcal{P}_{0} \backslash\{0\}\right) \cup\left(2+\mathcal{P}_{0}\right) .
\end{aligned}
$$

## $R \backslash\{0\}$ is partitioned into 6 parts

$$
\begin{array}{ll}
T_{0}=\{0\}, & T_{3}=\mathcal{U}_{0}, \\
T_{1}=\bigcup_{t \in \mathcal{T}\{1\}} t \mathcal{U}_{0}, & T_{4}=-\mathcal{U}_{0}, \\
T_{2}=\bigcup_{t \in \mathcal{T} \backslash\{1\}}\left(-t \mathcal{U}_{0}\right), & T_{5}=T_{6} \backslash\{0\}, \\
T_{6}=2+\mathcal{P}_{0} .
\end{array}
$$

## Theorem (Ikuta-M., 2017+)

(1) $\left\{T_{0}, T_{1}, \ldots, T_{6}\right\}$ defines a Schur ring on $\boldsymbol{G R}(4, e)$,
(2) The matrices

$$
\begin{aligned}
& A_{0}+\epsilon_{1} i\left(A_{1}-A_{2}\right)+\epsilon_{2} i\left(A_{3}-A_{4}\right)+A_{5}+A_{6} \\
& A_{0}+\epsilon_{1} i\left(A_{1}-A_{2}\right)+\epsilon_{2}\left(A_{3}+A_{4}\right)+A_{5}-A_{6}
\end{aligned}
$$

are the only hermitian complex Hadamard matrices in its Bose-Mesner algebra, where $\epsilon_{1}, \epsilon_{2} \in\{ \pm 1\}$.

## Proof

$$
\begin{array}{ll}
T_{0}=\{0\}, & T_{3}=\mathcal{U}_{0}, \\
T_{1}=\bigcup_{t \in \mathcal{T} \backslash\{1\}} t \mathcal{U}_{0}, & T_{4}=-\mathcal{U}_{0}, \\
T_{2}=\bigcup_{t \in \mathcal{T} \backslash\{1\}}\left(-t \mathcal{U}_{0}\right), & T_{5}=\mathcal{P}_{0} \backslash\{0\}, \\
T_{6}=2+\mathcal{P}_{0}
\end{array}
$$

## Theorem (Ikuta-M., 2017+)

(1) $\left\{T_{0}, T_{1}, \ldots, T_{6}\right\}$ defines a Schur ring on $\boldsymbol{G R}(4, e)$.

## Proof.

Compute the character sums ( $\chi=\chi_{b}$ : additive character of $\boldsymbol{R}$ )

$$
\sum_{\alpha \in T_{j}} \chi(a)=\sum_{\alpha \in T_{j}} \sqrt{-1}^{\operatorname{tr}(a b)} \quad\left(b \in T_{i}\right)
$$

show that this is independent of $\boldsymbol{b} \in \boldsymbol{T}_{\boldsymbol{i}}$, depends only on $\boldsymbol{i}$.

## Proof

## Theorem (Ikuta-M., 2017+)

(2) The matrices

$$
\begin{aligned}
& A_{0}+\epsilon_{1} i\left(A_{1}-A_{2}\right)+\epsilon_{2} i\left(A_{3}-A_{4}\right)+A_{5}+A_{6} \\
& A_{0}+\epsilon_{1} i\left(A_{1}-A_{2}\right)+\epsilon_{2}\left(A_{3}+A_{4}\right)+A_{5}-A_{6}
\end{aligned}
$$ are the only hermitian complex Hadamard matrices in its Bose-Mesner algebra, where $\epsilon_{1}, \epsilon_{2} \in\{ \pm 1\}$.

## Proof.

Suppose $\boldsymbol{H}=\sum_{\boldsymbol{i}=\mathbf{0}}^{\mathbf{6}} \boldsymbol{w}_{\boldsymbol{i}} \boldsymbol{A}_{\boldsymbol{i}}$ is a hermitian complex Hadamard matrix. Since the Bose-Mesner algebra is isomorphic to a subalgebra of the group ring of $\boldsymbol{R}$, the relation $\boldsymbol{H} \boldsymbol{H}^{*}=\boldsymbol{n} \boldsymbol{I}$ can be translated in terms of additive characters of $\boldsymbol{R}$. Then one obtains a system of quadratic equations in $\boldsymbol{w}_{\boldsymbol{i}}{ }^{\text {'s. }}$

## Example

$$
\begin{aligned}
H & =A_{0}+i\left(A_{1}+A_{3}\right)-i\left(A_{2}+A_{4}\right)+\left(A_{5}+A_{6}\right) \\
& \in\left\langle A_{0}, A_{1}+A_{3}, A_{2}+A_{4}, A_{5}+A_{6}\right\rangle .
\end{aligned}
$$

Smaller Schur ring defined by

$$
\begin{aligned}
T_{0} & =\{0\}, \\
T_{1} \cup T_{3} & =\bigcup_{t \in \mathcal{T}} t \mathcal{U}_{0}, \\
T_{2} \cup T_{4} & =\bigcup_{t \in \mathcal{T}}\left(-t \mathcal{U}_{0}\right), \\
T_{5} \cup T_{6} & =2 R \backslash\{0\} .
\end{aligned}
$$

This defines a nonsymmetric amorphous association scheme of Latin square type $L_{2^{e}, 1}\left(2^{e}\right)$ in the sense of Ito-Munemasa-Yamada (1991).

## Theorem (Ikuta-M. (2017+))

Let

$$
A_{0}+w_{1} A_{1}+\overline{w_{1}} A_{1}^{\top}+w_{3} A_{3}
$$

be a hermitian complex Hadamard matrix contained in the Bose-Mesner algebra $\mathcal{A}=\left\langle\boldsymbol{A}_{0}, \boldsymbol{A}_{1}, \boldsymbol{A}_{2}=\boldsymbol{A}_{1}^{\top}, \boldsymbol{A}_{3}\right\rangle$ of a $\mathbf{3}$-class nonsymmetric association scheme. Then $\mathcal{A}$ is amorphous of Latin square type $\boldsymbol{L}_{a, 1}(a)$, and $\boldsymbol{w}_{1}= \pm i, w_{3}=1$.

This can be regarded as a nonsymmetric analogue of

## Theorem (Goethals-Seidel (1970))

Let

$$
H=A_{0}+A_{1}-A_{2}
$$

be a (real) Hadamard matrix contained in the Bose-Mesner algebra $\mathcal{A}=\left\langle\boldsymbol{A}_{\mathbf{0}}, \boldsymbol{A}_{\mathbf{1}}, \boldsymbol{A}_{\mathbf{2}}\right\rangle$ of a 2-class symmetric association scheme. Then $\mathcal{A}$ is (amorphous) of Latin or negative Latin square type.
